- Describe your expectations from surgery
- Useful references

About this leaflet
We advise you to take your time to read this booklet, any questions you have please write them down on the sheet provided (towards the back) and we can discuss them with you at our next meeting. It is your right to know about the operations being proposed, why they are being proposed, what alternatives there are and what the risks are. These should be covered in this leaflet.

What is anterior vaginal wall prolapse?
Anterior means towards the front, so an anterior vaginal wall prolapse is a prolapse of the front wall of the vagina.
The correct name for an anterior vaginal wall prolapse is a cystocele (see diagram on following page).
The pelvic floor muscles are a series of muscles that form a sling or hammock across the opening of the pelvis. These muscles, together with their surrounding tissue, are responsible for keeping all of the pelvic organs (bladder, uterus, and rectum) in place and functioning correctly.
Prolapse occurs when the pelvic floor muscles or the vagina have become weak. This usually occurs because of damage at the time of childbirth but is most noticeable after the menopause when the quality of supporting tissue deteriorates.
When the anterior vaginal wall is weak the bladder pushes down into the vagina causing a bulge. This can be large and push out of the vagina especially on straining e.g. exercise or passing a motion.
A large cystocele can often cause or be associated with urinary symptoms such as urinary leakage, having to go frequently and sometimes difficulty in passing urine.
Some women have to push the bulge back into the vagina or lean forward in order to completely empty the bladder.
Occasionally women find that the bulge causes a dragging or aching sensation.
• **Ring pessary** - this is a soft plastic ring or device which is inserted into the vagina and pushes the prolapse back up. This usually gets rid of the dragging sensation and can improve urinary and bowel symptoms. It needs to be changed every six to nine months and can be very popular; we can show you an example in clinic. Other pessaries may be used if the ring pessary is not suitable. Some couples feel that the pessary gets in the way during sexual intercourse, but many couples are not bothered by it.

• **Shelf pessary or gellhorn** - If you are not sexually active this is a stronger pessary which can be inserted into the vagina and again needs changing every four to six months.

• **Pelvic floor exercises (PFE).** The pelvic floor muscle runs from the coccyx at the back to the pubic bone at the front and off to the sides. This muscle supports your pelvic organs (uterus, vagina, bladder and rectum). Any muscle in the body needs exercise to keep it strong so that it functions properly. This is more important if that muscle has been damaged. PFE can strengthen the pelvic floor and therefore give more support to the pelvic organs. These exercises may not get rid of the prolapse but they make you more comfortable. PFE are best taught by an expert who is usually a physiotherapist. These exercises have no risk and even if surgery is required at a later date, they will help your overall chance of being more comfortable.

**Alternatives to surgery**

• **Do nothing** – if the prolapse (bulge) is not distressing then treatment is not necessarily needed. If, however, the prolapse permanently protrudes through the opening to the vagina and is exposed to the air, it may become dried out and eventually ulcerate. Even if it is not causing symptoms in this situation it is probably best to push it back with a ring pessary.

**General risks of surgery**

• **Anaesthetic risk.** This is very small unless you have specific medical problems. This will be discussed with you.
• **Haemorrhage.** There is a risk of bleeding with any operation. The risk from blood loss is reduced by knowing your blood group beforehand and then having blood available to give you if needed. It is rare that we have to transfuse patients after their operation.

• **Infection.** There is a risk of infection at any of the wound sites. A significant infection is rare. The risk of infection is reduced by our policy of routinely giving antibiotics with major surgery.

• **Deep vein thrombosis (DVT).** This is a clot in the deep veins of the leg. The overall risk is at most four to five percent although the majority of these are without symptoms. Occasionally this clot can migrate to the lungs which can be very serious and in rare circumstances it can be fatal (less than one percent of those who get a clot). DVT can occur more often with major operations around the pelvis and the risk increases with obesity, gross varicose veins, infection, immobility and other medical problems. The risk is significantly reduced by using special stockings and injections to thin the blood (heparin).

**Specific risks of this surgery**

It is generally successful, however, five to fifteen per cent of women will develop recurrent prolapse. Some patients develop relapse in other parts of the vagina, which may require further surgery, other risks are as follows:

• **Bladder symptoms:** (urinary urgency and frequency) usually get better after the operation, but occasionally can start or worsen after the operation. If you experience urinary symptoms, please let us know so that we can treat you for it. Stress incontinence may develop in up to five per cent. Difficulties passing urine, needing self catheterisation postoperatively, may occur in one per cent of women. Urinary tract infection: affects one to five per cent of women.

• **Mesh exposure / extrusion:** affects up to 20% of women and presents as vaginal discharge, bleeding, and pain during sexual intercourse. Its treatment may include an operation to trim the eroded mesh. This can develop some years after the initial prolapse operation.

• **Mesh infection:** although uncommon, can be serious, requires antibiotic treatment. Rarely the mesh will need to be removed.

• **Damage to local organs:** this can include bladder, ureters (pipes from kidneys to the bladder) and blood vessels. This is a rare complication but requires that the damaged organ is repaired and this can result in a delay in recovery. It is sometimes not detected at the time of surgery and therefore may require a return to theatre. If the bladder is inadvertently opened during surgery, it will need catheter drainage for seven to 14 days following surgery. If the rectum (back passage) is inadvertently damaged at the time of surgery, this will be repaired, however, inserting the mesh may be delayed till a later date. This will require another operation, and in rare circumstances, a temporary colostomy may be required. (Colostomy: An opening made in the abdominal (tummy) wall to open up a section of the large bowel. A bag is placed over the colostomy to collect the waste products that would usually pass through the bowel and out of the body through the rectum and anus.) Very rarely further surgery can be required to close a fistula (a false passage between vagina and bladder or bowel) - affects one to two per 1000 cases.
• **Excessive bleeding:** requiring blood transfusion is uncommon less than one per cent but may require admission to ITU (Intensive Therapy Unit).

• **Pain on intercourse:** Up to 20% of women experience on-going vaginal pain and/or persistent pain during sexual intercourse, due to scarring, that may require further surgery. In rare circumstances the vagina may become too narrow so that intercourse cannot take place. Corrective surgery may be complex but could be an option in the circumstance.

Please note – this is a relatively new operation and long term information is not available.

**About the operation**

The operation was devised for those with severe or recurrent prolapse:

The long-term risks, complications and prolapse recurrence rate are uncertain. You are likely to feel more comfortable from a prolapse point of view. Intercourse may be more satisfactory and opening your bowels may be easier.

**How the operation is performed**

- The operation can be done with a spinal or general anaesthetic. You may have a choice of which anaesthetic is used.
- A spinal anaesthetic involves an injection in the lower back, similar to what we use when women are in labour or for a caesarean section. The spinal anaesthetic numbs you from the waist down. This removes any sharp sensation but a pressure sensation will still be felt.
- A general anaesthetic will mean you will be asleep (unconscious) during the entire procedure.
- The legs are placed in stirrups (supported in the air).
- Local anaesthetic is used in the wall of the vagina to separate different layers from each other and ease the separation of the vagina from the bladder.
- A vertical cut is made in the front wall of the vagina, over the area of the bulge:
• The vaginal skin is then separated from the bladder.
• The surgical dissection required is much more extensive than for a standard anterior prolapse operation and therefore surgical risks such as bleeding and bladder injury are slightly greater.
• The mesh is then positioned between the bladder and the vaginal wall and it is suspended in place using four arms that are positioned using special needles:

(Image courtesy CR Bard)
• The arms exit in the groin through two small cuts either side (around 1cm), and the vagina closed over the mesh.
• This then stops the bladder bulging into the front vaginal wall.

The vagina skin is stitched closed over the suspended mesh.

After the operation - in hospital
• On return from the operating theatre you will have a fine tube (drip) in one of your arm veins with fluid running through to stop you getting dehydrated.
• You may have a vaginal pack (surgical material to apply pressure) and a sanitary pad in place. This is to apply pressure to the wound to stop it oozing.
• If you have a catheter, it may give you the sensation as though you need to pass urine but this is not the case.
• Usually the drip, pack and catheter come out the morning after surgery or sometimes later the same day. This is not generally painful.
• The day after the operation you will be encouraged to get out of bed and take short walks around the ward. This improves general wellbeing and reduces the risk of clots in the legs.
• It is important that the amount of urine is measured the first couple of times you pass urine after the removal of the catheter. An ultrasound scan for your bladder may be done on the ward to make sure that you are emptying your bladder properly. If you are leaving a significant amount of urine in your bladder, you may have to have the catheter re-inserted back into your bladder for a couple of days more.
• To keep your blood thin and reduce the risk of blood clots, you may be given injections once a day until you go home or for longer in some cases.
• The wound is not normally very painful but sometimes you may require tablets or injections for pain relief.
• There will be slight vaginal bleeding like the end of a period and this may last for a few weeks.
• The nurses will advise you about sick notes, certificates etc. You are usually in hospital up to four days.

After the operation - at home
• Mobilisation is very important; using your leg muscles will reduce the risk of clots in the back of the legs (DVT), which can be very dangerous.
• You are likely to feel tired and may need to rest in the daytime from time to time for a month or more, this will gradually improve.
• It is important to avoid stretching the repair particularly in the first weeks after surgery. Therefore, avoid constipation and heavy lifting.

Avoiding constipation
– Drink plenty of water / juice
– Eat fruit and green vegetables esp broccoli
– Plenty of roughage e.g. bran / oats

The deep stitches dissolve during the first three months and the body will gradually lay down strong scar tissue over a few months.
• Do not use tampons for six weeks.
• There are stitches in the skin wound in the vagina. Any stitches under the skin will dissolve by themselves. The surface knots of the stitches may appear on your underwear or pads after about two weeks, this is quite normal. There may be little bleeding again after about two weeks when the surface knots fall off, this is nothing to worry about.

• At six weeks gradually build up your level of activity. After three months, you should be able to return completely to your usual level of activity.
• You should be able to return to a light job after about six weeks. Leave a very heavy or busy job until twelve weeks.
• You can drive as soon as you can make an emergency stop without discomfort, generally after three weeks, but you must check this with your insurance company, as some of them insist that you should wait for six weeks.
• You can start sexual relations whenever you feel comfortable enough after six weeks, so long as you have no blood loss. You will need to be gentle and may wish to use lubrication (such as KY jelly) as some of the knots on the internal stitches could cause your partner discomfort. You may, otherwise, wish to wait until all the stitches have dissolved, typically three to four months.
• Follow up after the operation is usually six weeks to six months. This may be at the hospital (with the doctor or the urogynaecology nurse), with your GP or by telephone. Sometimes follow up is not required.
Information about the British Society of Urogynaecology Surgical Database (Surgical Register)

The British Society of Urogynaecology (“BSUG”) is a national group of gynaecologists with a special interest and expertise in the treatment of incontinence and prolapse. BSUG has developed a database of clinical and surgical data for the purposes of publishing anonymous statistical information for research purposes and to enable individual NHS Trusts and consultants to audit information about operations to ensure that the procedures performed at their hospitals are as safe and effective as possible.

The patient information held in the BSUG database comprises name, hospital number and date of birth, together with clinical and surgical information (“patient identifiable data”). Because this information is confidential to each patient and is that patient’s personal data within the meaning of the Data Protection Act 1998, we do not disclose patient identifiable data to BSUG without written consent.

If you agree to allow us to enter your patient identifiable data into the BSUG database, please sign in the relevant section on the operation consent form.

The benefits the BSUG database may bring to you:

- Improving patient awareness of the outcomes of incontinence and prolapse surgery.
- Finding out how long the different operative procedures last.
- Helping to identify individual patients who have received an implant and where there may be a need for urgent clinical review.

The BSUG database will also be used to bring additional long-term benefits by:

- Providing feedback to gynaecological surgeons and teams to help maintain high clinical standards.
- Promoting open publication about the performance of implants used in operations.
- Providing feedback on implant performance to regulatory authorities.
- Providing feedback to suppliers about the performance of their implants.
- Monitoring and comparing the performance of hospitals.

Data collection – its security and confidentiality

The BSUG database uses an electronic system for data collection. The data is sent securely to a protected database, avoiding the need to send paper records through the post, to ensure your data receives maximum protection.

Your personal information is confidential and cannot be used outside of the BSUG database. Strict procedures are in place to protect your information and keep it confidential; it will only be available to you and your surgeon. If you wish, you can obtain access to a copy of your own record in accordance with the Data Protection Act 1998.
BSUG database Consent

I consent to:

1. the processing of my patient identifiable data for the research and auditing purposes described in this information sheet.

2. the disclosure by BSUGs of my patient identifiable data to its IT service provider or any future IT service provider, where such IT service provider has:
   (a) agreed to adopt appropriate technical and organisation measures to protect the security of my patient identifiable data and only to process it in accordance with BSUGDL’s instructions;
   (b) been instructed NOT to store my patient identifiable data on a server which is located outside of the United Kingdom; and
   (c) been informed of the existence of my legal right to confidence in respect of my patient identifiable data.

3. the disclosure of my patient identifiable data to the consultant team (and the NHS Trust employing that consultant team) who disclosed it to BSUG.

4. the disclosure of my patient identifiable data to BSUG or any legal entity which is wholly owned by BSUG, for processing in accordance with the consents in this section.

Your participation is voluntary

The form asks for your consent for your personal information to be recorded by the BSUG database. Your participation in the BSUG database is entirely voluntary. You can request access to view your entry on the BSUG database from your consultant team. If you agree and then change your mind, you may revoke this permission at any time by sending a written notice to your consultant OR to the address below. If you do not agree, your data will not be entered.

BSUG Database Limited

Comments, compliments, concerns or complaints

South Tees Hospitals NHS Foundation Trust is concerned about the quality of care you receive and strives to maintain high standards of health care.

However we do appreciate that there may be an occasion where you, or your family, feel dissatisfied with the standard of service you receive. Please do not hesitate to tell us about your concerns as this helps us to learn from your experience and to improve services for future patients.

Patient Advice and Liaison Service (PALS)

This service aims to advise and support patients, families and carers and help sort out problems quickly on your behalf.

This service is available, and based, at The James Cook University Hospital but also covers the Friarage Hospital in Northallerton, our community hospitals and community health services. Please ask a member of staff for further information.
