

Febrile Convulsion

You have been given this information leaflet because your child has been diagnosed with a febrile convulsion.

Febrile convulsions are fits or seizures that occur in a child with a high temperature. They are not epileptic seizures.

Around 1 in 20 children will have at least one febrile convulsion.

Most occur with common infections such as coughs and colds, or ear infections. Occasionally your child will have a more serious infection such as a kidney infection or pneumonia as the cause.

Symptoms of a febrile convulsion:

- Arm or leg twitching
- Whole body stiffness
- Your child may wet themselves
- Usually last less than 5 minutes
- Loss of consciousness
- Vomiting
- Eye rolling
- Sleepy after the event.

Investigation for a febrile convulsion

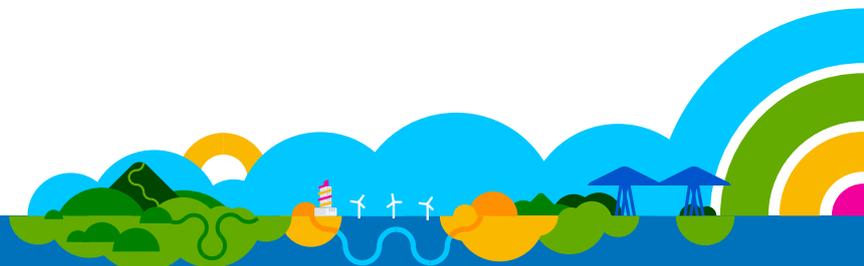

No investigations are required if your child has made a quick recovery, with a simple febrile convulsion, and a clear focus of infection.

Children with complex febrile convulsions or serious causes of infection need to be admitted to hospital for further tests.

Treatment of a febrile convulsion

- If your child is fitting lay them in the recovery position.
 - Lay them on their side, with their faced turned to one side and head lifted up
 - This will help prevent the swallowing of any vomit or blockage of the airway
- Avoid placing your fingers in their mouth.
- When the seizure stops try to cool your child.
- If it is a first seizure, lasted longer than 5 minutes or they have not recovered quickly take them to the nearest hospital, or dial 999.

Following a febrile convulsion

Seeing a child having a seizure can be frightening and distressing for parents. However, almost all children make a complete recovery with no after-effects.

There is a small link to developing epilepsy in later life, a 1 in 50 chance. And a future febrile convulsion is more likely under the age of 15 months.
