

Viral Induced Wheeze in Children

You have been given this information leaflet because your child has been diagnosed with a viral induced wheeze.

Wheezing is a whistling sound that occurs during breathing when the airways are narrowed, it is more frequent when breathing out. Wheeze in babies and young children is a common symptom of a viral infection. Some children wheeze on and off in their early childhood during viral infections.

It does not mean your child has asthma. They may have frequent episodes and never develop asthma.

As your child has been diagnosed with a viral illness they may also suffer from the following:

- Runny nose
- Temperatures
- Vomiting
- Diarrhoea
- Cough and breathlessness

Treating viral induced wheeze

No specific treatment exists. You may be provided with an inhaler, but this does not always work.

You should care for your child by:

- Ensuring they drink plenty of fluids.
- If breast fed, continue to do so.
- If your child is coughing and vomiting, then give smaller feeds more frequently.
- If your child has a temperature or sore throat, you can give paracetamol. Please check the medication label prior to giving to your child.
- Not smoking near the child as this may irritate the lungs further and exacerbate the illness.

The cold-like symptoms may normally last 3-4 days. Your child may suffer with a cough and wheeze for up to 2 weeks.

continued over the page

You should seek medical attention if any of the following symptoms occur:

- Severe breathing difficulties.
- Blue skin or lips.
- Unusually sleepy.
- Unable to take oral fluids due to vomiting or difficulty in breathing.
- Your child has not drunk anything all day or not passed urine.
